FILTERED IN-BOX FOR VOICE MAIL, E-MAIL, PAGES, WEB-BASED INFORMATION, AND FAXES

FIELD OF THE INVENTION

1

5

10

15

20

The present invention is directed to a method for organizing, prioritizing, and displaying incoming message information on a wireless device.

BACKGROUND OF THE INVENTION

In recent years, the functionality of wireless devices has expanded far beyond simple voice or pager communications. Wireless devices can now receive a variety of incoming messages including pages, e-mails, faxes, voicemails, and short message services such as weather or sports updates. In some cases the actual message, for example a voicemail, is not delivered directly to the wireless device due to memory, bandwidth, or other limitations, but rather a notification message is sent to the wireless device to notify the user that a message has arrived and is being stored at a remote location. These type of notification messages are known in the art as shown in U.S. Patent No. 5,797,103, "Method and Apparatus For Informing A Remote Unit Of A Feature-Originated Call", incorporated herein by reference. The notification messages, as well as some actual messages, are generally stored within the wireless device. However, most wireless devices are only equipped with a small screen that

displays a few short lines of text or small graphics. To view each item that has been sent to

the wireless device, the user generally must scroll through a series of screens or menus and

the wheless device, the user generally must seron through a series of screens of menus and

may be forced to examine all of the items of a particular type, or sometimes all of the items regardless of type in order to find the message of interest. Most wireless devices can be set to

alert the user that a new message has arrived, but this feeture is not year, useful if it is also in

alert the user that a new message has arrived, but this feature is not very useful if it is alerting

the user every few moments that something new has arrived. The user is likely to begin ignoring the alert or simply turn it off. This may result in important messages going unnoticed among a large number of unimportant messages.

For example, a user may subscribe to a number of services for his wireless device, including paging, a sports score service, and e-mail. With all of these services active on a typical evening when a variety of sporting events are in progress, the user may be receiving several messages every few minutes. If during this time the user receives an important page or e-mail from his or her boss, the message may go unnoticed among all the other messages and the user may miss an important work assignment.

The user of a wireless device can be easily overwhelmed when trying to keep track of and prioritize the myriad pieces of information that are arriving at any given time. It would be desirable for the wireless device to be able to organize the incoming information in such a way that the user can quickly and easily recognize and distinguish between important and unimportant items.

SUMMARY OF THE INVENTION

5

10

15

20

25

The present invention provides a method for automatically organizing and prioritizing the incoming messages on a wireless communication device and displaying the messages accordingly. A predetermined set of rules is used to perform the organization and prioritization of the incoming messages. When a message arrives, it is analyzed to determine certain classification information about the message. This classification information is then used to organize the incoming message among the messages that are already being stored on or referenced on the wireless device. This information is also used to determine the priority of the incoming message. Depending on the level of priority assigned to the incoming message, the wireless device may alert the user that the new message has arrived or may just store the message for the next time the user chooses to check for messages. The wireless

device may also update its display to reflect the various classification information that has been gathered about the messages presently being stored.

The present invention allows the user of a wireless communication device to subscribe to any number of services that send messages to the device, but the user maintains control over the way the incoming messages are handled to prevent being overwhelmed with information.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 illustrates a wireless network such as may be used with an embodiment of the present invention.

Fig. 2 is a flowchart illustrating one possible implementation of the method of the present invention.

Fig. 3 is a flowchart illustrating an alternative implementation of the method of the present invention.

DETAILED DESCRIPTION

5

10

15

20

25

The present invention could be implemented within a wireless network similar to that depicted in Fig. 1. A wireless device 101 communicates with a wireless infrastructure 102 that is connected to a variety of public and private networks including the Public Switched Telephone Network (PSTN) 103 and the Internet 104. The user of the wireless device subscribes to a variety of information services that send messages of various formats or types to the wireless device via one of the networks to which wireless infrastructure 102 is connected. These services can include, but are not limited to, email, paging, voice mail, fax, and short message services (including short message based information services). These messages can originate from a variety of equipment such as telephone 105, fax machine 106, computer terminal 107, or network server 108 depending on the type of message. The

equipment that sends the message will vary based on the type of message and some messages may pass through more than one type of equipment before delivery to the wireless device. For example, an individual may leave a voicemail message for the user of the wireless device from telephone 105, but the voicemail will likely be stored on Private Branch Exchange (PBX) equipment 109 or telephone company equipment 110 and the device storing the voicemail will send a notification message to the wireless device to inform the user that the voicemail has arrived. Additionally, some types of messages can be sent from more than one type of equipment. For example, faxes may be sent from either fax machine 106 or computer terminal 107 if it is equipped with fax software.

Fig. 2 illustrates one possible way of implementing the present invention where much of the processing of the incoming messages is performed in the wireless infrastructure. A message for the user of wireless device 101 is received by wireless infrastructure 102 (step 201). The wireless infrastructure then retrieves a set of rules corresponding to the user for which the message is intended from a database either co-located with the wireless infrastructure or at a remote location and accessible to the wireless infrastructure via a computer network (step 202). Using these rules, the wireless infrastructure analyzes the message and determines classification information about the message (step 203). Based on this classification information, the wireless infrastructure can assign a priority to the message if desired; and if this priority is not very high the wireless infrastructure may elect not to send the alert message to the device, instead saving the alert message for later retrieval (step 204, 205). If the priority is sufficiently high, the wireless infrastructure sends an alert message to the wireless device containing the classification information about the received message (step 206). This alert message can optionally contain part or the entire contents of the original message along with the classification information. Once the wireless device receives the alert message, it organizes and prioritizes the incoming message with the messages already stored on the wireless device using the classification information and pre-assigned priority

information (if available) associated with the incoming message and the classification information that was previously determined for and associated with each of the stored messages (step 207). The wireless device then checks to see if the incoming message has been designated of a sufficient priority level to alert the user of the wireless device that it has arrived (step 208). If so, the wireless device can select a customizable or user-defined alert type such as ringing, beeping, or vibrating, based on the classification information (step 209). The wireless device alerts the user using the selected method (step 210). The display of the wireless device may also be updated to reflect that a new message has arrived such as by the display of standard or user-defined icons or sounds, the display of summarized message counts by type, or the display of the actual message itself as determined by the message priority and user-defined settings (step 211).

25

The method of the present invention as illustrated in Fig. 2 could also be implemented in another device on the network to which the wireless infrastructure could route the incoming messages for processing before passing them on to the wireless device.

Alternatively, all of the processing could be done on the wireless device itself as illustrated by the flowchart in Fig. 3. The wireless device receives an incoming message from the wireless infrastructure (step 301). The wireless device then retrieves a predetermined set of rules corresponding to the user of the wireless device from its own memory or alternatively from a database somewhere else in the network (step 302). The incoming message is then analyzed using the predetermined set of rules to determine classification information (step 303). Using this classification information, the wireless device organizes the incoming message with the messages already stored on the wireless device (step 304). The wireless device also employs the predetermined rules to determine whether the incoming message is of sufficient priority to alert the user that it has arrived (step 305). If it is of sufficient priority, then the wireless device alerts the user using well known methods (step 306). In either case, the wireless device updates its display to reflect the

incoming message (step 307).

5

10

15

20

25

The rule sets of the present invention used to determine the classification information are typically predetermined by the user of the wireless device. The user can input and modify these rules using any of a variety of well known systems including calling into an interactive voice response system or a system that responds to touch tone key presses, using software carried on the wireless device itself, or using a computer interface via the Internet or World Wide Web. These rules could be very simple in nature, with the user's choices limited to a few very general rules based on a few criteria, for example, message type or message origin. Alternatively, the user could be given the option of creating sophisticated rules that would allow the incoming messages to be searched for key words or phrases, or that would use different rules depending on time of day, day of the week, source of message, etc. The present invention could also be implemented with nested categories. For example, all email messages could be grouped under an "email" category and within that category the email messages could be grouped again as "work" or "personal" email.

For example, one potential rule would analyze an incoming email message and extract the email address of the originator. This address could then be cross-referenced with a built-in address book on the wireless device to locate the category that the individual corresponding to the email address has been classified under in the address book. The email message could then be classified under the same category.

The kind of classification information that can be obtained from the incoming message will vary based on the type or format of the message, but typical information may include type, origin, time received, and size. Certain message formats, such as email, can provide further information including, for example, full text searching of the content of the message. More sophisticated systems could be implemented to search voicemail messages for keywords through the use of voice recognition technology. Those of skill in the art will easily be able to determine additional kinds of information that can be extracted from

Hellebust et al.

incoming messages for use as classification information based on the type of message.

5

10

15

The display of the wireless device can be updated to inform the user of the results of the classification, organization, and prioritization steps in a variety of ways. The display of the wireless device could show the number of messages under each of the categories defined by the rule sets. Alternatively, the display could organize the messages by priority level, time received, or any other externally defined or user-defined item of classification information.

The method of the present invention can be implemented using any well known programming language and techniques. The implementation on the wireless device may be particularly suited to using Wireless Application Protocol (WAP) Forum defined standards, such as Wireless Markup Language (WML). The use of rule sets to organize messages is well known in the field of email software. Products like Microsoft Outlook 97 employ rules to direct incoming email messages to particular folders within the user's email box. Those of skill in the art will recognize how to implement the rule sets of the present invention to function in a similar fashion but without being limited to any one type of message.

The present invention is not limited to the specific embodiments described. It is expected that those skilled in the art will be able to devise other implementations that embody the principles of the present invention and remain within its scope.
